TN_130 FT232H Errata Technical Note

Document Reference No.: FT_000405
Version 1.2
Issue Date: 2013-03-15

The intention of this errata technical note is to give a detailed description of known functional or electrical issues with the FTDI FT232H devices.

The current revision of the FT232H is revision C, launched March 2013.

Use of FTDI devices in life support and/or safety applications is entirely at the user’s risk, and the user agrees to defend, indemnify and hold harmless FTDI from any and all damages, claims, suits or expense resulting from such use.

1 FT232H Revision

FT232H part numbers are listed in Table 1. The letter at the end of date code on the device markings identifies the device revision.

The current revision of the FT232H is revision C, launched March 2013. At the time of releasing this Technical Note there is one known minor issue with this silicon revision. A workaround is provided for this issue.

3 Functional Issues of FT232H

3.1 Revision A

3.1.1 Error switching from 245 FIFO mode to MPSSE mode

Introduction:
The FT232H may switch from one of the EEPROM configurable modes to MPSSE mode during runtime by calling the FT_SetBitMode call in the software application.

Issue:
If the device is configured to be in 245 FIFO mode (external EEPROM) and the application switches the mode to MPSSE, spurious accesses to the RD# or WR lines can cause the MPSSE protocol to corrupt. This only affects the device if 245 FIFO mode is the operational state defined in the external EEPROM.

Workaround:
Assuming 245 FIFO mode was not required prior to accessing MPSSE then selecting UART mode in the external EEPROM would prevent the problem.

This issue is corrected at silicon revision B.

Package specific:
The affected packages are listed in Table 3.

</tr>
</tbody>
</table>

Table 3

3.1.2 Incorrect status reported on FT1248 MISO line when SS_n is inactive

Introduction:
The FT232H has an FT1248 mode. This mode uses a MISO line to indicate the status of the device (e.g. buffers full / empty)

Issue:
The bug is minor and system will not lose data but the status while SS_n is inactive can indicate that data can be written or read. However when starting a command the status on the MISO line on the clock cycle after the command is not correct.

Workaround:
Ignore the status on the MISO line on the cycle after the command and only look at the ACK status on the data phase of the FT1248. This will correctly reflect the status which was present while SS_n was inactive.
### Package specific:

The effected packages are listed in Table 4.

Table 6
4 Electrical and Timing specification deviations of FT232H

4.1 Revision A

4.1.1 Suspend Timer Failure

Introduction:
The FT232H has the ability to be put into suspend by the host to conserve power usage.

Issue:
The USB specification chapter 9 compliance tests require the device to go into suspend within 3.125ms. The device is taking up to 4ms to enter suspend state.

Workaround:
This issue is corrected at silicon revision B.

Package specific:
The effected packages are listed in Table 5.

<table>
<thead>
<tr>
<th>Package</th>
<th>Applicable (Yes/No)</th>
</tr>

<td>Y</td>
</tr>
<tr>
<td>FT232HQ</td>
<td>Y</td>
</tr>
</tbody>
</table>

Table 7
4.1.2 Internal 3V3 Regulator

Introduction:
The FT232H uses an internal regulator to generate 3V3 from a 5V source (VREGIN). The source should be variable from 3V3 to 5V.

Issue:
The supply to the regulator must not drop below 4.3V for the correct 3V3 regulated output to be produced. This only affects self-powered designs where the only board supply is 3V3.

Workaround:
VREGIN must not be supplied below 4.3V. VREGIN can be powered via the USB bus supply with VCCIO, VPLL and VPHY powered with 3.3 volts.

Package specific:
The effected packages are listed in Table 6.

<table>
<thead>
<tr>

4.2 Revision B

4.2.1 Internal 3V3 Regulator

Introduction:
The FT232H uses an internal regulator to generate 3V3 from a 5V source (VREGIN). The source should be variable from 3V3 to 5V.

Issue:
The supply to the regulator must not drop below 4.3V for the correct 3V3 regulated output to be produced. This only affects self-powered designs where the only board supply is 3V3.

Workaround:
VREGIN must not be supplied below 4.3V. VREGIN can be powered via the USB bus supply with VCCIO, VPLL and VPHY powered with 3.3 volts.

Package specific:
The effected packages are listed in Table 7.
